## Nobel Prize lessons – Discoveries that laid the foundation for mRNA vaccines

---

The 2023 medicine prize honours discoveries that were decisive in the development of effective mRNA vaccines for COVID-19 during the pandemic that struck the world in early 2020. The two laureates' ground-breaking research has fundamentally changed our understanding of how mRNA interacts with the immune system. It contributed to the extraordinarily rapid development of new vaccines during the coronavirus pandemic.

```
LA TERMINAL DE R
```

```
-bash: r: command not found
```

Que quiere decir que no existe el comando "r" ya

De igual forma al poner `ls r` (incluyendo el `ls`) te dirá que no existe el comando `r`, aunque `ls` sí sea un comando.

La práctica hace al maestro: a continuación veremos algunos de los comandos básicos, pero para practicar más, la primera tarea será resolver los siguientes cursos prácticos:

- Terminar el curso [Learn the Command Line de Codecademy](#)
- Adentrarse en el mundo del [shell](#) (curso de bash).

### La terminal de R

R es un programa que funciona con la línea de comandos y por lo tanto puede correrse desde la terminal de varias formas o en su propia terminal:

## Abstract

Life is that which replicates and evolves. The origin of life is also the origin of evolution. A fundamental question is when do chemical kinetics become evolutionary dynamics? Here, we formulate a general mathematical theory for the origin of evolution. All known life on earth is based on biological polymers, which act as information carriers and catalysts. Therefore, any theory for the origin of life must address the emergence of such a system. We describe prelife as an alphabet of active monomers that form random polymers. Prelife is a generative system that can produce information. Prevolutionary dynamics have selection and mutation, but no replication. Life marches in with the ability of replication: Polymers act as templates for their own reproduction. Prelife is a scaffold that builds life. Yet, there is competition between life and prelife. There is a phase transition: If the effective replication rate exceeds a critical value, then life outcompetes prelife. Replication is not a prerequisite for selection, but instead, there can be selection for replication. Mutation leads to an error threshold between life and prelife.

The term "resilience" has risen in popularity following a series of natural disasters, the impacts of climate change, and the Covid-19 pandemic. However, different disciplines use the term in widely different ways, resulting in confusion regarding how the term is used and difficulties operationalising the underlying concept. Drawing on an overview of eleven disciplines, our paper offers a guiding framework to navigate this ambiguity by suggesting a novel typology of resilience using an information-theoretic approach. Specifically, we define resilience by borrowing an existing definition of individuals as sub-systems within multi-scale systems that exhibit temporal integrity amidst interactions with the environment. We quantify resilience as the ability of individuals to maintain fitness in the face of endogenous and exogenous disturbances. In particular, we distinguish between four different types of resilience: (i) preservation of structure and function, which we call "strong robustness"; (ii) preservation of function but change in structure ("weak robustness"); (iii) change in both structure and function ("strong adaptability"); and (iv) change in function but preservation in structure ("weak adaptability"). Our typology offers an approach for navigating these different types and demonstrates how resilience can be

### ABSTRACT

Filamentous cyanobacteria can show fascinating examples of nonequilibrium self-organization, which, however, are not well understood from a physical perspective. We investigate the motility and collective organization of colonies of these simple multicellular lifeforms. As their area density increases, linear chains of cells gliding on a substrate show a transition from an isotropic distribution to bundles of filaments arranged in a reticulate pattern. Based on our experimental observations of individual behavior and pairwise interactions, we introduce a nonreciprocal model accounting for the filaments' large aspect ratio, fluctuations in curvature, motility, and nematic interactions. This minimal model of active filaments recapitulates the observations, and rationalizes the appearance of a characteristic length scale in the system, based on the Péclet number of the cyanobacteria filaments.
